# Outline for Today

- Intuition on classification with decision tree
- Impurity-based feature importance metrics
- Building decision trees based on impurity reduction
- Feature importance and explainable AI

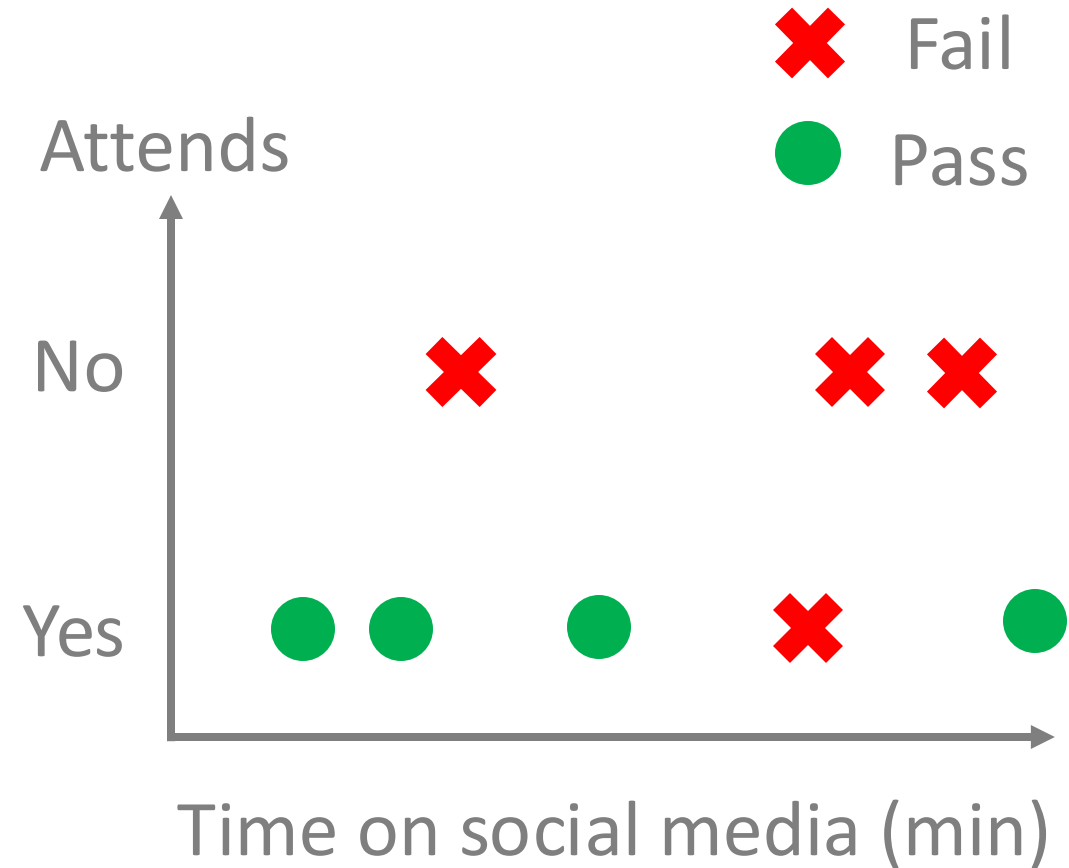

# Datasets and Tree-based Classification

Dataset from my Lecture

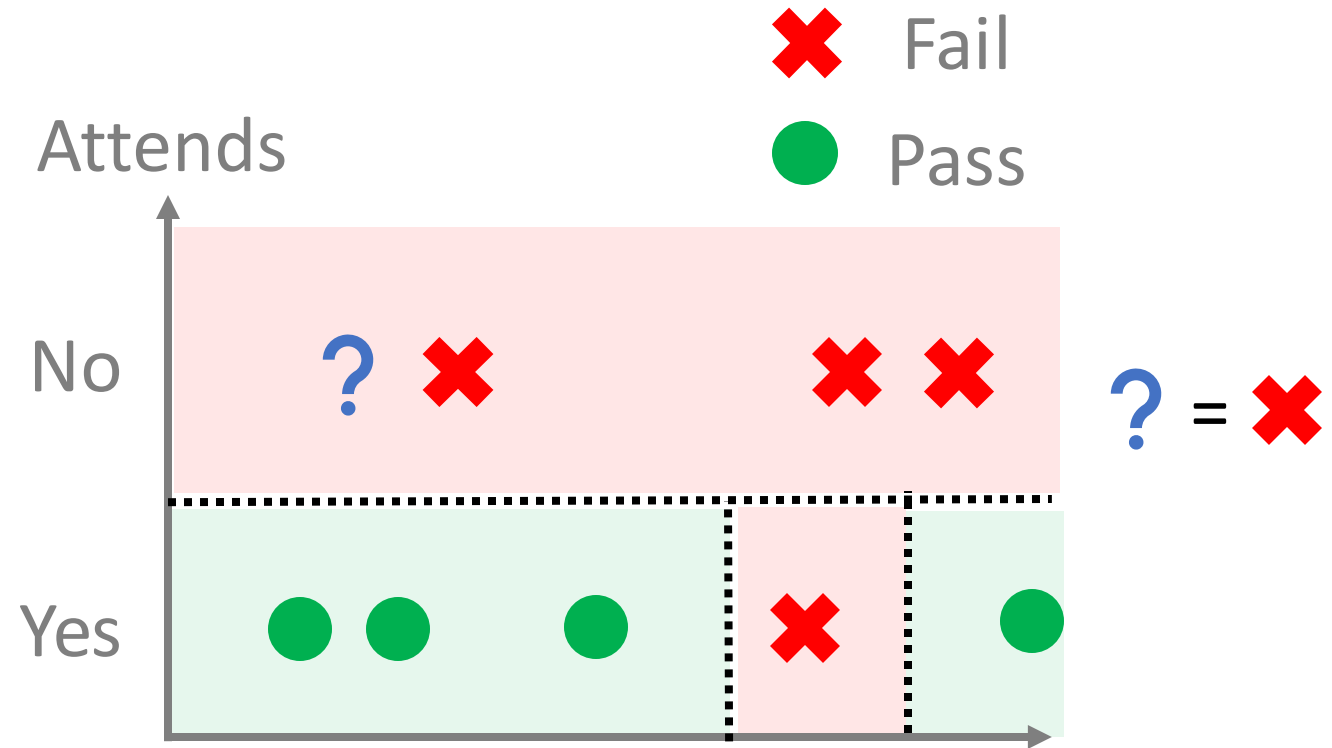

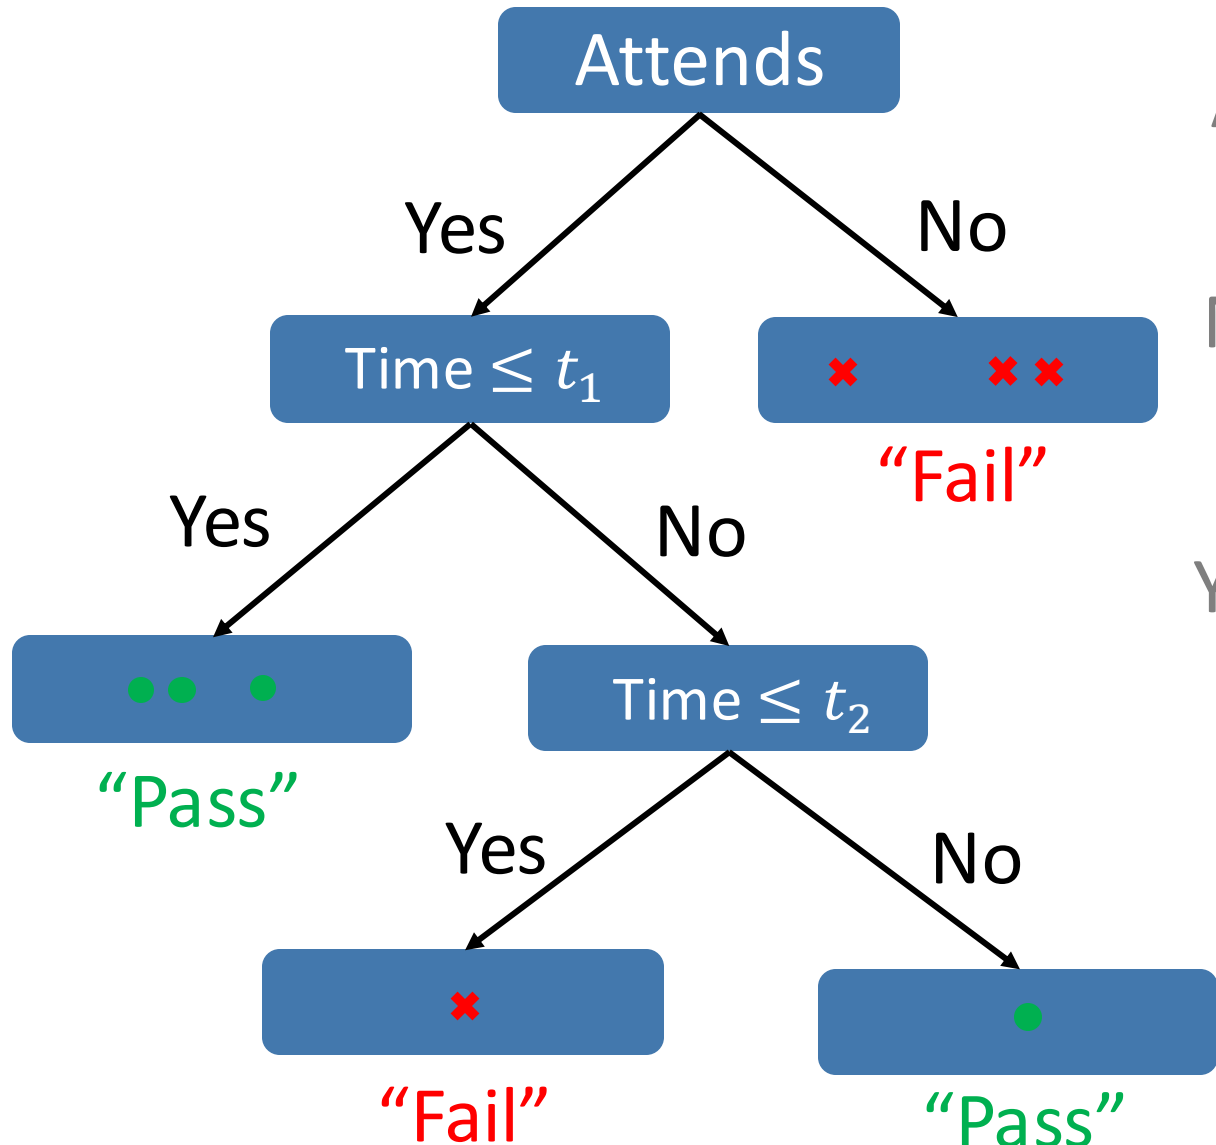

Social Media Time (min)	Attends Class	Passed the Midterm
30	Yes	Pass
80	Yes	Pass
140	Yes	Pass
50	Yes	Pass
110	No	Fail
60	No	Fail
100	Yes	Fail
120	No	Fail

Continuous      Categorical

Features      Label

# Datasets and Tree-based Classification

Time on social media (min)

Successively find splits of the data to create decision regions

Greedy, recursive partitioning

# Finding the Best Split Criterion

Social Media Time (min)	Attends Class	Passed the Midterm	
30	Yes	Pass	←
80	Yes	Pass	←
140	Yes	Pass	←
50	Yes	Pass	←
110	No	Fail	←
60	No	Fail	←
100	Yes	Fail	←
120	No	Fail	←

Is attendance our best split?

# Gini Impurity: Definition

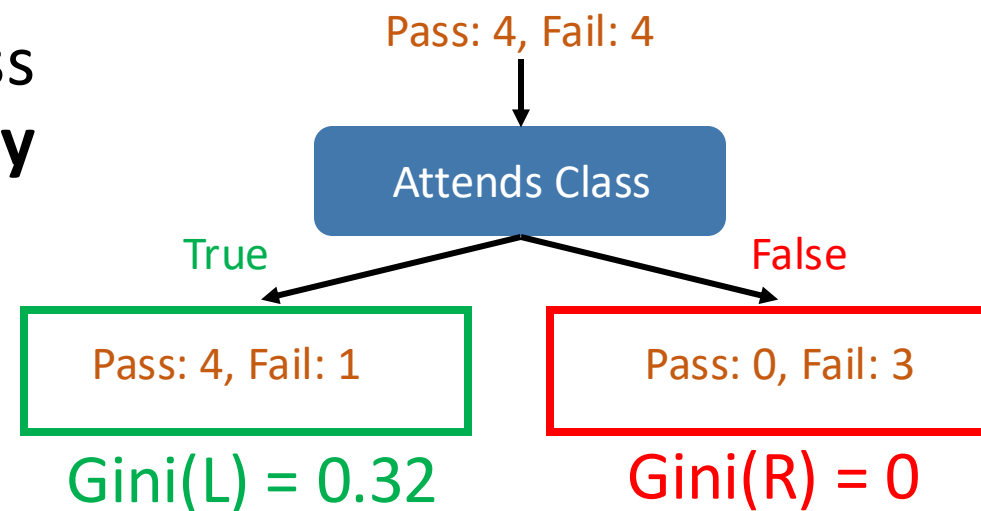

Given a node with  $K$  classes and class probabilities  $p_1, \dots, p_k$ . The **Gini Impurity** is defined as

$$Gini(Node) = 1 - \sum_{k=1}^K p_k^2.$$

Here:  $1 - (p_{pass}^2 + p_{fail}^2)$

$$p_{pass} = \frac{4}{5}, p_{fail} = \frac{1}{5}$$

$$p_{pass} = \frac{0}{3}, p_{fail} = \frac{3}{3}$$

In our example:

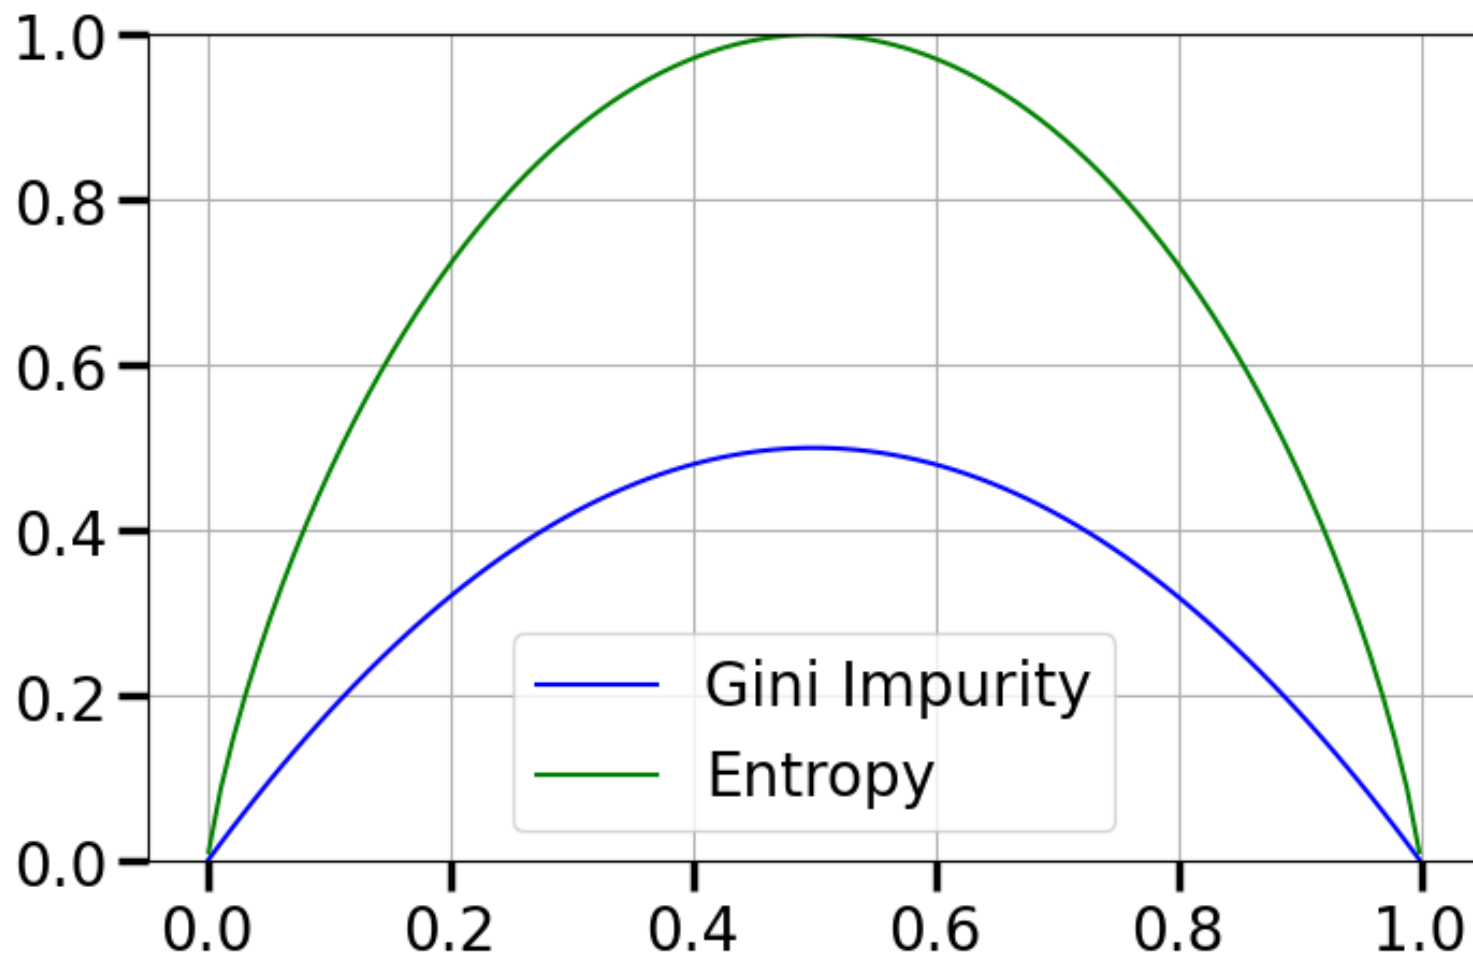

- True branch:  $Gini(L) = 1 - \left(\frac{4}{5}\right)^2 - \left(\frac{1}{5}\right)^2 = 0.32$

- False branch:  $Gini(R) = 1 - (0)^2 - (1)^2 = 0$

*Gini of a pure split is zero*

# Gini Impurity and Entropy

Impurity

Alternative to Gini:

**Entropy** =  $-\sum_k p_k \log_2 p_k$ ,  
with  $p_k$  : proportion of data  
from class  $k$  in the node.

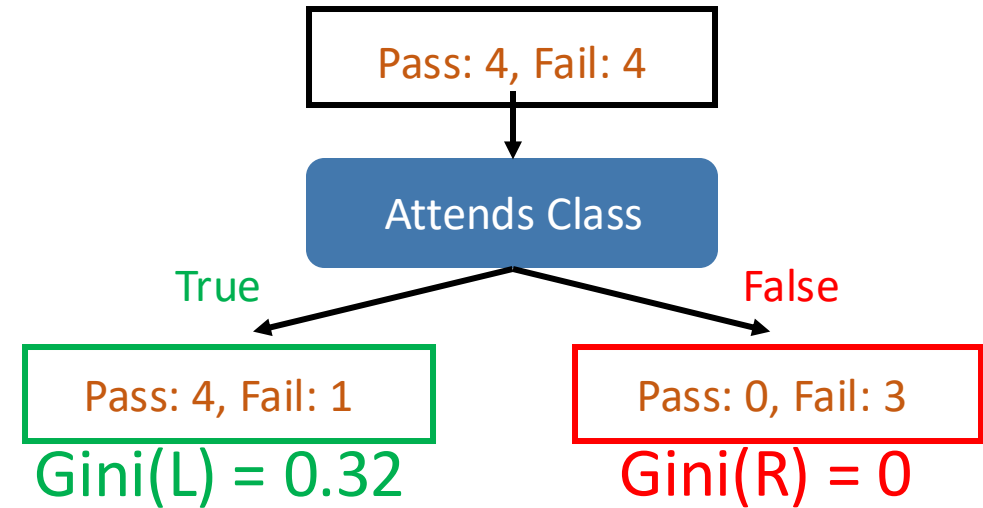

Proportion of Positive Class

# Gini Impurity of the Entire Split

When evaluating a split, we compute the **weighted Gini of the children**:

$$Gini_{split} = \frac{n_L}{n} Gini(L) + \frac{n_R}{n} Gini(R)$$

→ 8

→ 5

→ 3

$$Gini_{split} = 0.2$$

$$Gini_{split} = \frac{5}{8} * 0.32 + \frac{3}{8} * 0 = 0.2$$

# Gini Impurity on Continuous Values

Goal: Identify the best splitting threshold

Social Media Time (min)	Passed the Midterm
30	Pass
50	Pass
60	Fail
80	Pass
100	Fail
110	Fail
120	Fail
140	Pass

1. Sort ascending

2. Identify where class changes

3. Take average as threshold

$\leq 55$

$\leq 70$

$\leq 90$

$\leq 130$

# Gini Impurity on Continuous Values

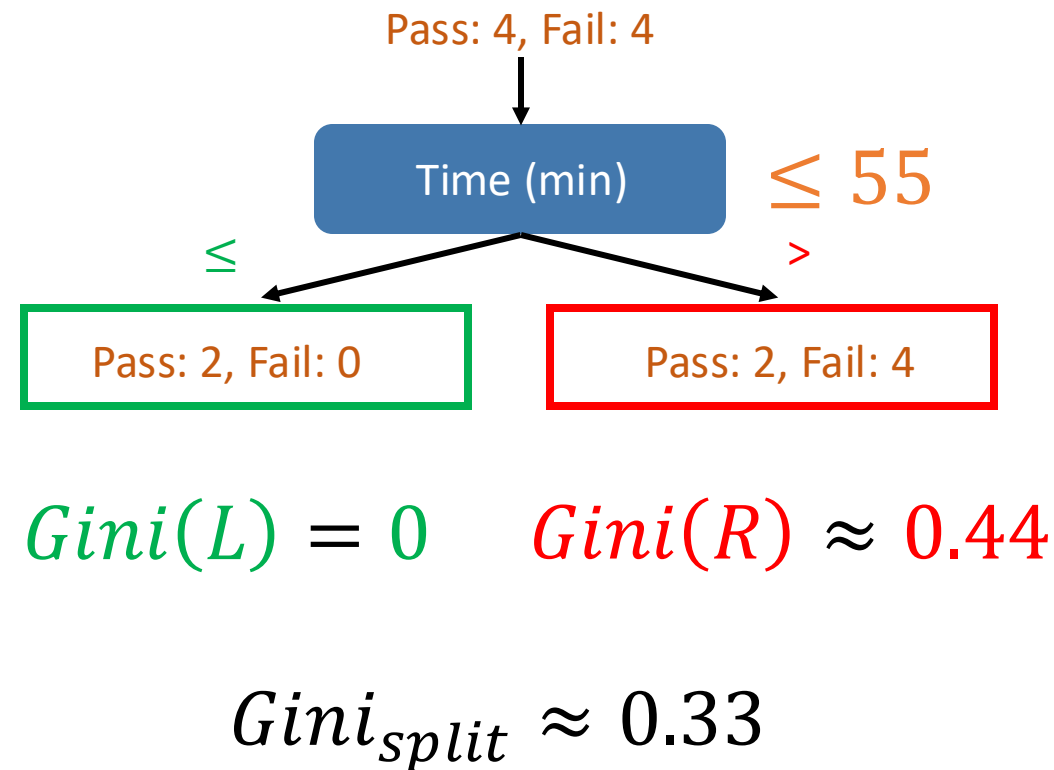

Social Media Time (min)	Passed the Midterm
30	Pass
50	Pass
60	Fail
80	Pass
100	Fail
110	Fail
120	Fail
140	Pass

→ 0.33

→ 0.48

→ 0.38

→ 0.44

# Impurity Reduction to Choose the Best Split

Choose the split that causes the maximum **impurity reduction**  $\Delta i(\text{split})$ :

$$\Delta i(\text{split}) = \max(Gini_{\text{parent}} - Gini_{\text{split}})$$

Pass: 4, Fail: 4

Attends

$$Gini_{\text{parent}} = 1 - \left(\frac{1}{2}\right)^2 - \left(\frac{1}{2}\right)^2 = 0.5$$

is fixed  $\rightarrow$  find lowest  $Gini_{\text{split}}$

Gini impurity over all possible splits:

$$Gini_{\text{Attends}} = 0.2$$

$$Gini_{\text{Time} \leq 55} = 0.33$$

$$Gini_{\text{Time} \leq 70} = 0.48$$

$$Gini_{\text{Time} \leq 90} = 0.38$$

$$Gini_{\text{Time} \leq 130} = 0.44$$

$$\Delta i(\text{Attends}) = 0.5 - 0.2 = 0.3$$

# From Trees to Explainable AI

Decisions in the tree are:

- Human-interpretable
- Verifiable
- We can ask “What if?”  
(Counterfactuals)

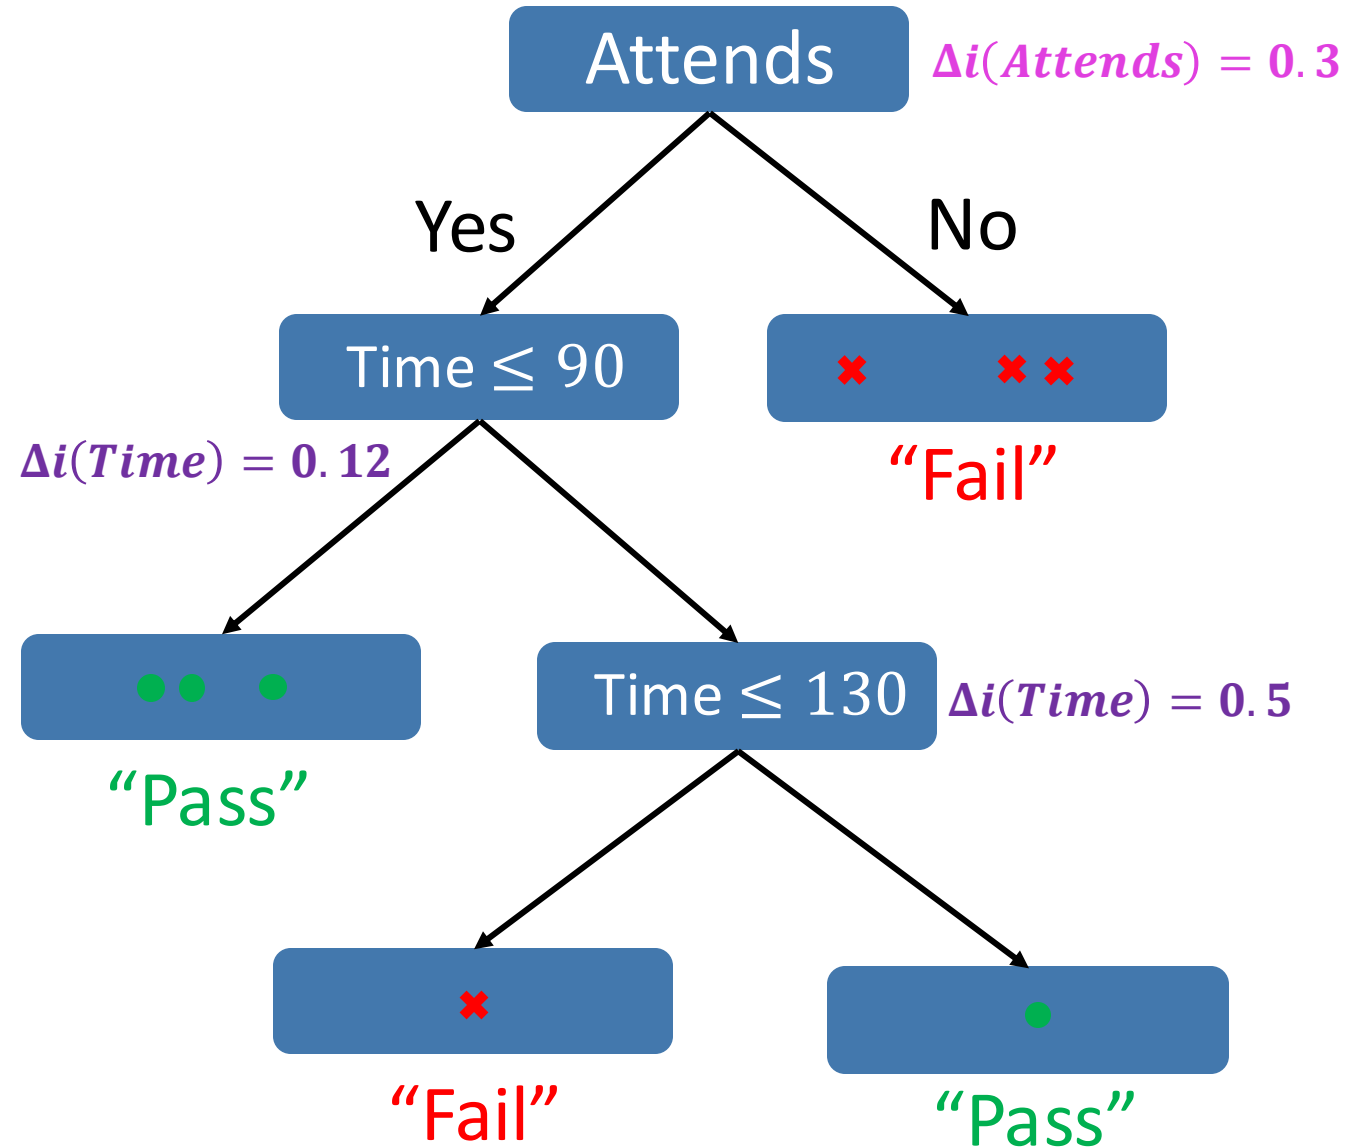

# Impurity-based Feature importance

We calculate the **importance** of a feature  $f$  in a tree as:

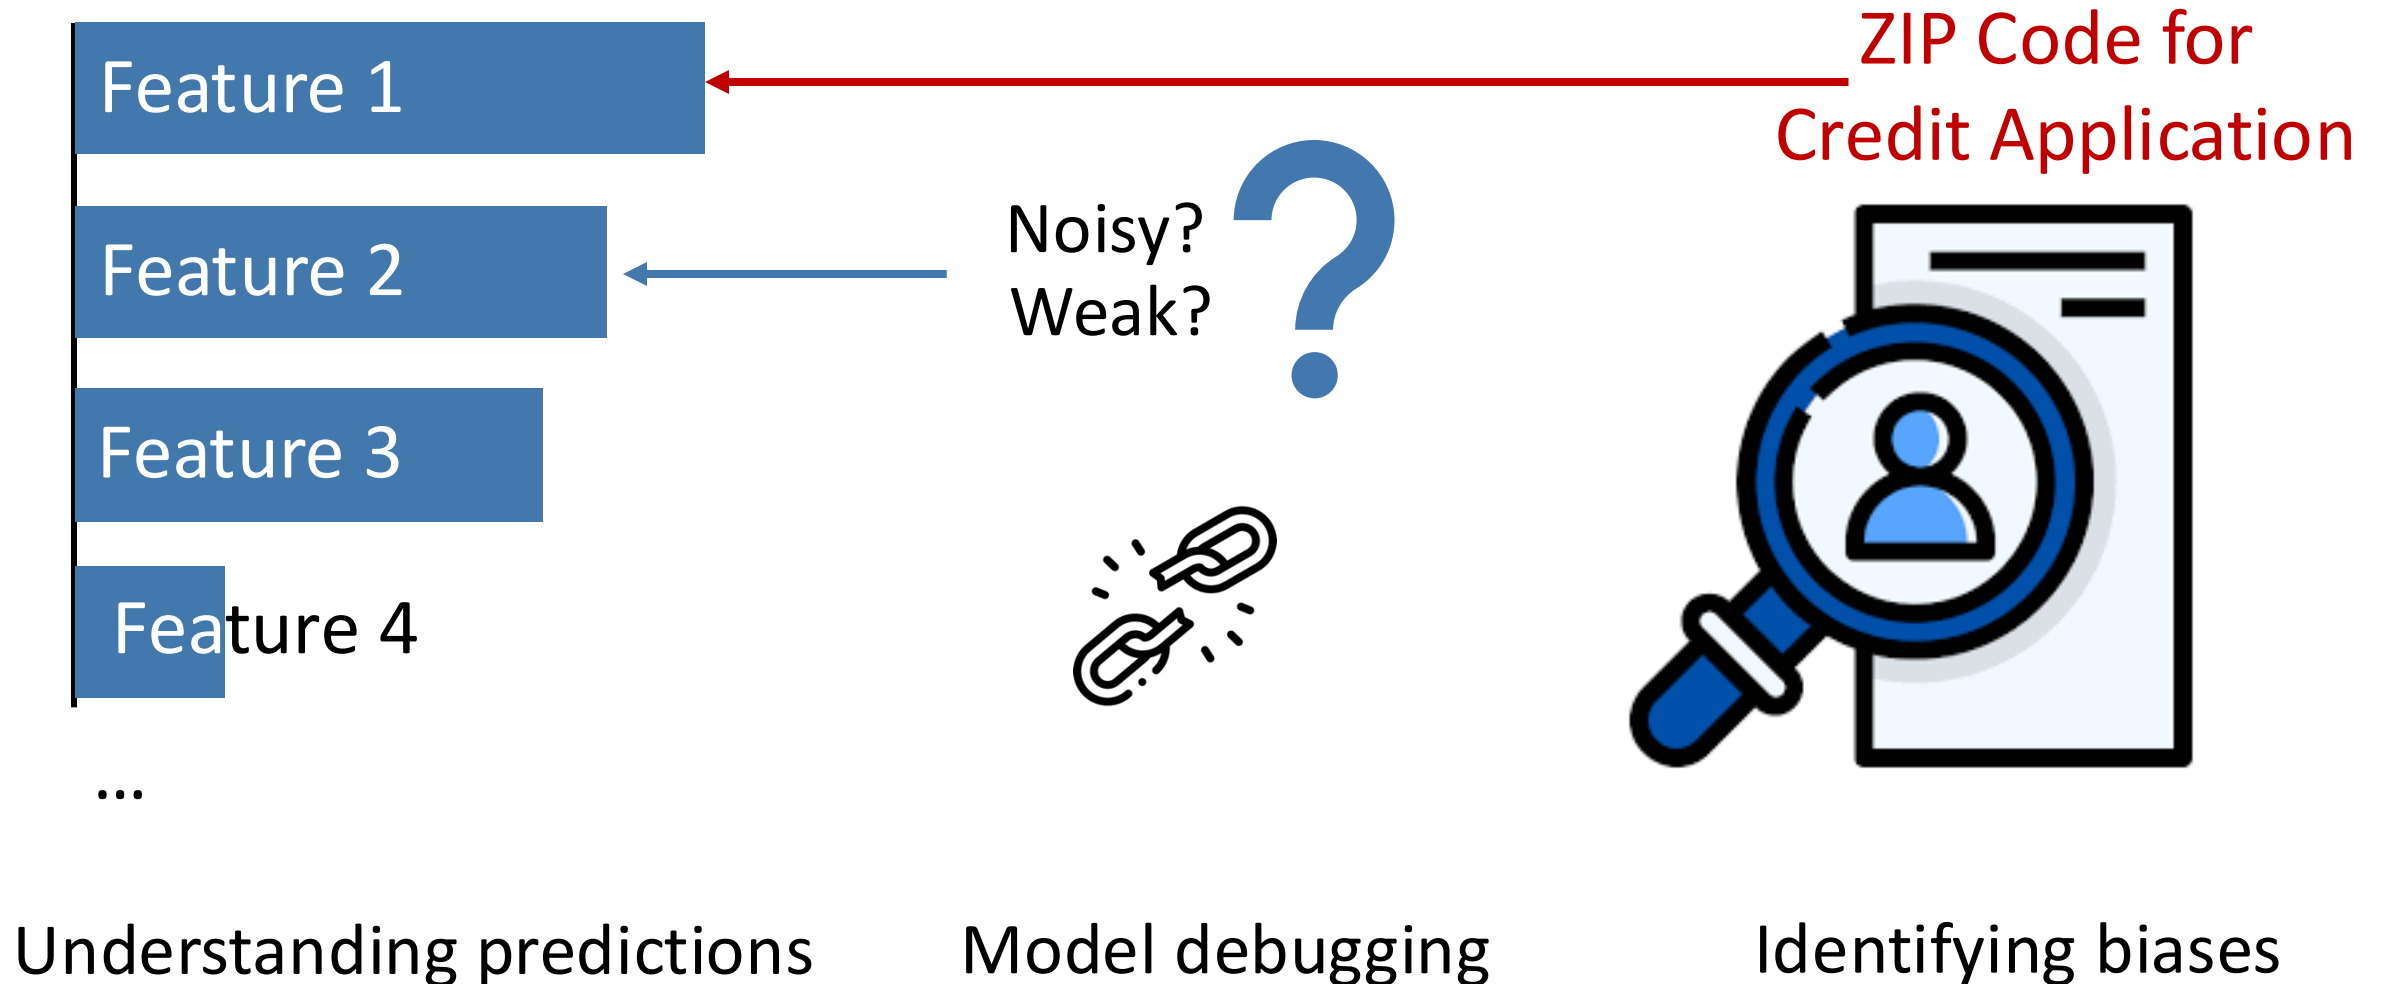

$$Importance(f) = \frac{\sum_{t \in \text{Splits on } f} \Delta i(t)}{\sum_{s \in \text{All splits}} \Delta i(s)}.$$

$$Importance(Attends) = \frac{0.3}{0.3 + 0.12 + 0.5} \approx 32.6\%$$

$$Importance(Time) = \frac{0.12 + 0.5}{0.3 + 0.12 + 0.5} \approx 67.4\%$$
